Centering separates residual uncertainty from estimation error

Average the centered expansion Previous slide: pointwise squared-error expansion

$$\|z-a\|^2 = \|r\|^2 + 2r^T(m-a) + \|m-a\|^2$$

Take $E[\cdot\,|y]$; $m-a$ is fixed

$$E[r|y] = E[z|y] - m = 0 \qquad V = \mathrm{Cov}[z|y]$$

$$E[r^T(m-a)|y] = E[r|y]^T(m-a) = 0 \qquad E[\|r\|^2|y] = \sum_{j=1}^{d} E[r_j^2|y] = \mathrm{tr}\, V$$

Conditional squared-error risk

$$R(a|y) = \mathrm{tr}\, V + \|m-a\|^2$$

block(height: 1.1cm)[

- Risk is residual uncertainty plus squared distance from the posterior mean.
